

Part II Project: Progress Report

Martin Walls

Project overview

Achieved work

- ▶ Rust parser generator: LALRPOP
- ▶ Custom lexer, to handle `typedef` definitions (context-sensitivity).

Achieved work

- ▶ Defined three-address code representation
- ▶ For each node in the AST, define transformation to three-address code
- ▶ Complexity:
 - ▶ Switch statement logic: fall-through and default cases
 - ▶ Assignment: evaluating an expression either as loading a value or storing to that address

Achieved work

Implemented the Relooper algorithm

- ▶ Turning the linear sequence of IR instructions into a structure of ‘blocks’

Achieved work

Target code generation

- ▶ Memory layout:
 - ▶ Pushing/popping function call stack frames
 - ▶ Updating stack and frame pointers
 - ▶ Allocating addresses for variables

Achieved work

NodeJS runtime:

- ▶ Instantiate WebAssembly module
- ▶ Initialise memory, and store program arguments
- ▶ Implemented some of the C standard library, e.g. `printf`

Achieved work

IR optimisation:

- ▶ Tail-call optimisation
 - ▶ Find recursive tail-calls in each procedure
 - ▶ Instead, set the parameter variables to the new values and loop back to the entry point
- ▶ Unreachable procedure elimination
 - ▶ Generate call graph
 - ▶ Walk call graph, marking all reached functions
 - ▶ Remove all unmarked functions
