

# C to WebAssembly Compiler

---

Martin Walls

## Project overview

# Main compiler pipeline

- Rust parser generator: LALRPOP
- Custom lexer, to handle typedef definitions (context-sensitivity).
- Avoiding ambiguities e.g. dangling else

# Main compiler pipeline

- Defined three-address code representation
- For each node in the AST, defined transformation to three-address code
- Complexity:
  - Switch statement logic: fall-through and default cases
  - Assignment: evaluating an expression either as loading a value or storing to that address

# Main compiler pipeline

Implemented the Relooper algorithm

- Turning the linear sequence of IR instructions into a structure of 'blocks'

Simple

Loop

Multiple

# Main compiler pipeline

## Target code generation

- Defined WebAssembly instructions for each IR instruction
- Pushing/popping function call stack frames
- Updating stack and frame pointers
- Allocating addresses for variables

# Main compiler pipeline

## NodeJS runtime:

- Instantiate WebAssembly module
- Initialise memory, and store program arguments
- Implemented some of the C standard library, e.g. `printf`

# Implemented optimisations

- Tail-call optimisation
  - Find recursive tail-calls in each procedure
  - Instead, set the parameter variables to the new values and loop back to the entry point
- Unreachable procedure elimination
  - Generate call graph
  - Walk call graph, marking all reached functions
  - Remove all unmarked functions

# Optimised stack allocation
